- Capacitors with a dielectric

## 25-2 Calculating the Capacitance: Cylindrical Capacitor

### 1. Use Gauss's law

$$q = \epsilon_0 EA = \epsilon_0 E(2\pi rL)$$

### 2. Find potential

$$V = \int_{-}^{+} E ds = -\frac{q}{2\pi\epsilon_0 L} \int_b^a \frac{dr}{r} = \frac{q}{2\pi\epsilon_0 L} \ln\left(\frac{b}{a}\right)$$

$$C = 2\pi\epsilon_0 \frac{L}{\ln(b/a)} \quad (\text{cylindrical capacitor}).$$

## 25-4 Energy Stored in an Electric Field

# Energy Storage in Capacitors

We want to calculate **potential energy** stored in the capacitor

**VERYYYYYY** hard

$$U = U_{1-2} + U_{1-3} + \dots + U_{1-10} + U_{2-1} + U_{i-j} \text{ of every other pair}$$

Easier way!

Move a tiny charge,  $dq$ , from negative plate to positive plate →

It moves through a potential difference  $\Delta V \rightarrow$  its potential energy increases by an amount

$$dU = dq\Delta V_C$$

$$\& \Delta V_C = \frac{q}{C}$$

The instantaneous charge on the plates is  $\pm q$ .

The charge escalator does work  $dq \Delta V$  to move charge  $dq$  from the negative plate to the positive plate.

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Addison-Wesley.

$$dU = \frac{q dq}{C}$$

$$U = \frac{1}{C} \int_0^Q q dq = \frac{1}{2} \frac{Q^2}{C}$$

✓ **Energy** storage in terms of the charge on the plates:

$$U = \frac{1}{2} \frac{Q^2}{C}$$

✓ **Energy** storage in terms of the voltage across the plates:

$$Q = CV$$

$$U = \frac{1}{2} CV^2$$

✓ **Energy density:**

The potential energy of a charged capacitor may be viewed as being stored in the electric field between its plates.

Energy density → Potential energy per unit volume between the plates

For parallel-plate capacitor →

$$u = \frac{U}{Ad} =$$

$$\rightarrow u = \frac{1}{2} \epsilon_0 \left( \frac{V}{d} \right)^2 = \frac{1}{2} \epsilon_0 E^2$$

## A collection of various electronic components including capacitors, resistors, and connectors. The components are arranged on a light-colored surface. There are two large electrolytic capacitors: a blue Nichicon 4700µF 35V and a silver Vitamin Q 4700µF 35V. There are several smaller electrolytic capacitors, including a black 35V 4700µF and a blue 35V 4700µF. There are also several resistors, including a green 224K 100V, an orange 103K 500V, and several smaller orange resistors with values like 10, 15, and 151. There are also some connectors, including a D-sub connector and a BNC connector.

## 25-5 Capacitor with a Dielectric

If the space between the plates of a capacitor is completely filled with a **dielectric material**, the capacitance  $C$  in vacuum (or, effectively, in air) is multiplied by the material's **dielectric constant**  $\kappa$ , which is a number greater than 1.

$$C = \kappa C_{air}$$

If the **potential difference** between the plates of a capacitor is maintained, as by the presence of battery B →

$V = \text{a constant}$

(a)

Copyright © 2014 John Wiley & Sons, Inc. All rights reserved.

The effect of a dielectric is to increase the charge on the plates.

$$q = CV = \kappa C_{\text{air}} V$$

$$q = \kappa q_{\text{air}}$$

If the charge on the capacitor plates is maintained, as in this case by isolating the capacitor→

$q = \text{a constant}$

The effect of a dielectric is to reduce the potential difference between the plates.

$$V = \frac{q}{C} = \frac{q}{\kappa C_{air}} \rightarrow$$

$$V = \frac{V_{air}}{\kappa}$$

The scale shown is that of a potentiometer, a device used to measure potential difference (here, between the plates). A capacitor cannot discharge through a potentiometer.

In a region completely filled by a dielectric material of dielectric constant  $\kappa$ , all electrostatic equations containing the permittivity constant  $\epsilon_0$  are to be modified by replacing  $\epsilon_0$  with  $\kappa\epsilon_0$ .

## Examples:

The magnitude of electric field produced by a point charge inside a dielectric→

$$E = \frac{1}{4\pi\kappa\epsilon_0} \frac{q}{r^2}$$

The magnitude of electric field outside an isolated conductor immersed inside a dielectric→

$$E = \frac{\sigma}{\kappa\epsilon_0}$$

# Dielectrics: An Atomic View

What happens in atomic view when we put a dielectric in an electric field?

1. Polar dielectric
2. Nonpolar dielectric

# 1. Polar dielectrics

Copyright © 2014 John Wiley & Sons, Inc. All rights reserved.

Molecules with a permanent electric dipole moment, showing their random orientation in the absence of an external electric field.

Copyright © 2014 John Wiley & Sons, Inc. All rights reserved.

An electric field is applied, producing partial alignment of the dipoles. Thermal agitation prevents complete alignment.

## 2. Nonpolar dielectrics

The initial electric field inside this nonpolar dielectric slab is zero.

(a)

The applied field aligns the atomic dipole moments.

(b)

The field of the aligned atoms is opposite the applied field.

(c)

## Dielectrics: An Atomic View

The effect of both polar and nonpolar dielectrics is to weaken any applied field within them.

To sum up →

$$Q = C_0 V_0$$

(b)

$$Q = CV$$

$$C > C_0$$

$$V < V_0$$

$$E < E_0$$

Can find the force using  $F_x = -dU/dx$  and

Fringe Electric Field pulls the dielectric into the gap

This section we talked about:

## Chapter 25

*See you on Friday*
