Today:

- Introduction to magnetism
- Electric force vs magnetic force on charges
- Vector cross product
- Consequences of magnetic force

Magnetism

The needle of a compass is a small magnet.

Electric Force on Charges

Electric force acts on a charge regardless of its motion.

$$\vec{F}_E = q\vec{E}$$

$$\left\{ \begin{array}{l} \text{Magnitude: } F_E = qE \\ \text{Direction: direction of } \vec{E} \end{array} \right.$$

Magnetic Force on Charges

**Magnetic force
acts only on a
moving charge.**

$$\vec{F}_B = q \vec{v} \times \vec{B} \quad \left\{ \begin{array}{l} \text{Magnitude: } F_B = qvB \sin \alpha \\ \text{Direction: RH rule} \end{array} \right.$$

The Vector Cross Product

Point the fingers of your right hand along the first vector in the cross product (vector C), then curl them so they point along the second vector (vector D). Your thumb gives the direction of the cross product.

The Vector Cross Product

So $\vec{C} \times \vec{D}$ points up and $\vec{D} \times \vec{C}$ points down.

$$|\vec{C} \times \vec{D}| = |\vec{C}| |\vec{D}| \sin \alpha$$

Cross product vs regular product

Regular/dot product

Distributive

$$\vec{B} \cdot (\vec{C} + \vec{D}) = \vec{B} \cdot \vec{C} + \vec{B} \cdot \vec{D}$$

Commutative

$$CD = DC$$

$$\vec{C} \cdot \vec{D} = \vec{D} \cdot \vec{C}$$

Associative

$$B(CD) = (BC)D$$

Cross product

Distributive

$$\vec{B} \times (\vec{C} + \vec{D}) = \vec{B} \times \vec{C} + \vec{B} \times \vec{D}$$

Anticommutative

$$\vec{C} \times \vec{D} = -\vec{D} \times \vec{C}$$

Non-Associative

$$\vec{B} \times (\vec{C} \times \vec{D}) \neq (\vec{B} \times \vec{C}) \times \vec{D}$$

Unit vector notation

The cross product becomes easy to deal with when using unit vector notation

$$\vec{A} = A_x \hat{i} + A_y \hat{j} + A_z \hat{k}$$

$$\vec{B} = B_x \hat{i} + B_y \hat{j} + B_z \hat{k}$$

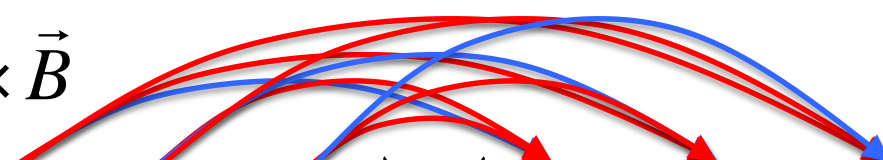

$$\hat{i} \times \hat{j} = \hat{k}$$

$$\hat{j} \times \hat{k} = \hat{i}$$

$$\hat{k} \times \hat{i} = \hat{j}$$

Now let's see what the cross product between A and B is:

$$\vec{C} = \vec{A} \times \vec{B}$$

$$\vec{C} = (A_x \hat{i} + A_y \hat{j} + A_z \hat{k}) \times (B_x \hat{i} + B_y \hat{j} + B_z \hat{k})$$

$$\vec{C} = (A_y B_z - A_z B_y) \hat{i} + (A_z B_x - A_x B_z) \hat{j} + (A_x B_y - A_y B_x) \hat{k}$$

Another way to think about it

Start with the two vectors in component form

$$\vec{A} = A_x \hat{i} + A_y \hat{j} + A_z \hat{k}$$

$$\vec{B} = B_x \hat{i} + B_y \hat{j} + B_z \hat{k}$$

The cross product is given by the determinant of the following matrix:

$$\vec{C} = \vec{A} \times \vec{B} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix}$$

$$\vec{C} = (A_y B_z - A_z B_y) \hat{i} + (A_z B_x - A_x B_z) \hat{j} + (A_x B_y - A_y B_x) \hat{k}$$

Parallel and Perpendicular vectors

For parallel vectors

$$\vec{A} = A\hat{i} \quad \vec{B} = B\hat{i} \quad \vec{C} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ A & 0 & 0 \\ B & 0 & 0 \end{vmatrix} = \vec{0}$$

For perpendicular vectors

$$\vec{A} = A\hat{i} \quad \vec{B} = B\hat{j} \quad \vec{C} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ A & 0 & 0 \\ 0 & B & 0 \end{vmatrix} = AB\hat{k}$$

TopHat questions

Top Hat Question

A charged particle q enters a region with a constant B-field pointing into the page as shown. If the particle follows the path from **a** to **b** as shown

$$\vec{F} = q\vec{v} \times \vec{B}$$

What is the sign of q ?

A. Positive

A. Negative

A. Not enough info

Top Hat Question

A charged particle q enters a region with a constant B-field pointing into the page. The force on the charged particle is

$$\vec{F} = q\vec{v} \times \vec{B}$$

As the particle travels from point **a** to point **b**, its kinetic energy:

A. Should increase

A. Should decrease

A. Should stay the same

A. Not enough info

Cyclotron Motion

Charged particles in uniform magnetic fields undergo **uniform circular motion**.

The radius of the circle depends on how fast the particle is moving:

$$\vec{F}_B = q\vec{v} \times \vec{B}$$

$$|\vec{F}_B| = |q|vB \sin \alpha = |q|vB$$

The magnetic force is the **net force**

$$|\vec{F}_B| = m \frac{v^2}{R}$$

Cyclotron Motion

$$|\vec{F}_B| = |q| \cancel{v} B = m \frac{v^{\cancel{2}}}{R}$$

$$R = \frac{mv}{|q|B}$$

The magnetic force is always perpendicular to \vec{v} , causing the particle to move in a circle.

Cyclotron Motion

$$v = \frac{2\rho R}{T_{cyc}}$$

T_{cyc} is the cyclotron period (time it takes to make one cycle)

$$R = \frac{mv}{|q|B}$$

~~$$R = \frac{m}{|q|B} \frac{2\rho R}{T}$$~~

$$T_{cyc} = \frac{2\pi m}{|q|B}$$

The period (and also the frequency of the cyclotron) depend on the B-field strength and the charge-to-mass ratio q/m

$$f_{cyc} = \frac{|q|B}{2\pi m}$$

The Aurora

Earth's Van Allen belt
(aurora borealis/australis)

(a) Charged particles spiral around the magnetic field lines.

(b) The earth's magnetic field leads particles into the atmosphere near the poles, causing the aurora.

(c) The aurora

Application: Mass Spectrometer

$$r = \frac{mv}{qB} = \frac{x}{2}$$

$$m^2 = \frac{q^2 B^2 x^2}{4v^2}$$

$$m^2 = \frac{q^2 B^2 x^2}{4} \frac{m}{2qV}$$

$$m = \frac{qB^2 x^2}{8V}$$

$$\Delta K = -\Delta U \quad \frac{1}{2}mv^2 = qV$$

$$v^2 = \frac{2qV}{m}$$

Application: Cyclotron

In the gap between the dees, charges are accelerated by E-field:

$$\Delta K_{\text{gap}} = -\Delta U_{\text{gap}} = q\Delta V$$

After N times through the gap:

$$\frac{1}{2}mv^2 = Nq\Delta V$$

$$v = \sqrt{\frac{2Nq\Delta V}{m}}$$

$$r = \frac{mv}{qB} = \frac{m}{qB} \sqrt{\frac{2Nq\Delta V}{m}}$$

$$= \sqrt{\frac{2Nm\Delta V}{qB^2}}$$

The protons spiral outward in a cyclotron, picking up energy in the gap.
